₇ 1 Introduction

$_{*}$ 2 Methodology

9 2.1 Model Setup

- MECCA box model as described in Coates and Butler (2015) to broadly simulate the
 Benelux (Belgium, Netherlands and Luxembourg) region. Solar zenith angle of 51°N was
 used to determine photolysis rates through a parameterisation and the SZA chosen is
 broadly representative of the central Benelux region.
- MECCA box model has been updated to include vertical mixing with the free troposphere
 and accordingly includes a diurnal cycle for the PBL height. These amendments are
 discussed further in Sect. 2.3.
- Simulations start at 06:00 using spring ecquinoctical conditions and the simulations ended after two days.
- All simulations performed using the Master Chemical Mechanism, MCM v3.2, (Rickard et al., 2015) and also repeated using MOZART-4 (Emmons et al., 2010). Coates and Butler (2015) describes the implementation of both MCM v3.2 and MOZART-4 for use with KPP within MECCA.

Table 1: The variables and their minimum and maximum values that were systematically varied in this study are outlined in this table.

Variable	Minimum Value	Maximum Value	Unit
Temperature	288 (15)	313 (40)	K (°C)
NO_x emissions			$\mathrm{molecules~cm^{-3}~s^{-1}}$
NMVOC emissions			$\mathrm{molecules~cm^{-3}~s^{-1}}$
Solar Zenith Angle (SZA)			°N
Humidity			%

- NOx and other parameters were varied systematically to analyse the effects on ozone mixing ratios over different NOx gradients and hence different atmospheric conditions.
- VOC emissions constant until noon of first day, to simulate a plume of emitted VOC.
- Two sets of runs were performed to include both a temperature dependent and independent source of biogenic VOC emissions. MEGANv2.1 (Guenther et al., 2012) was used to specify the temperature dependent BVOC emissions of isoprene and monoterpenes, the BVOC considered in this study.

• Methane is fixed at 1.7 ppmv throughout the model run, carbon monoxide (CO) and ozone were initialised at 200 ppbv and 40 ppbv and then allowed to evolve freely throughout the the simulation.

3 2.2 VOC Emissions

30

31

32

- Anthropogenic emissions from Benelux were obtained from the TNO-MACC_III emission inventory. TNO-MACC_III is the current version of the TNO-MACC_II inventory and was created using the same methodology as (Kuenen et al., 2014) and based upon improvements to the existing emission inventory during the AQMEII 2 exercises described in Pouliot et al. (2015).
- Temperature independent emissions of the biogenic VOC isoprene and monoterpenes, were calculated as a fraction of the total anthropogenic VOC emissions from each country in the Benelux region, this data was obtained from the supplementary data available from the EMEP (European Monitoring and Evaluation Programme) model (Simpson et al., 2012).
- AVOC and BVOC emissions are included as total emissions from SNAP (Selected Nomenclature for Air Pollution) source categories and these emissions were assigned to

Table 2: Anthropogenic NMVOC emissions in 2011 in tonnes from each SNAP category assigned from TNO-MACC_III emission inventory and biogenic VOC emission in tonnes from Benelux region assigned from EMEP. The allocation of these emissions to each MCM v3.2 and MOZART-4 species is found in the supplement.

	SNAP1	SNAP2	SNAP34	SNAP5	SNAP6	SNAP71

chemical groupings based on the country specific profiles for Belgium, the Netherlands and Luxembourg provided by TNO.

- The MCM v3.2 initial species were determined using the country specific profiles for each SNAP source category and where appropriate information of individual chemical species that can be represented by MCM v3.2 were determined using the speciations of Passant (2002).
 - After calculating the MCM v3.2 initial VOC and respective emissions were assigned to the respective MOZART-4 species and the emissions in MOZART-4 were weighted by the carbon numbers of the MCM v3.2 species and the emitted MOZART-4 species.

Table 3: Belgium AVOC and BVOC emissions, in molecules cm⁻² s⁻¹, mapped to MCM v3.2 species.

The total MCM v3.2 emissions for each initial species in Tables 3, 4 and 5 were translated to emissions of MOZART-4 species by weighting with the carbon numbers. The final emissions of the MOZART-4 species representing each MCM v3.2 species are presented in Table 6 for each country in the Benelux region.

58 2.3 Vertical Mixing with Diurnal Boundary Layer Height

- The base boxmodel (Sect. 2.1) includes a constant boundary layer height of 1 km and no interactions (mixing) with the free troposphere.
- A parameterisation of the diurnal profile of the planetary boundary layer (PBL) height over
 Los Angeles was provided by Boris Bonn based on data from the CARES field campaign
 (CARB, 2008).

• The PBL height was calculated at every time point for the model run and then read into
the boxmodel at each time point .

• The concentrations of the chemical species within the PBL are diluted due to the larger mixing volume when the PBL height increases at the beginning of the day, also the increasing PBL height induces mixing of chemical species from the free troposphere with those chemical

species within the PBL i.e. vertical mixing. When the PBL height collapses during night

giving the stable nocturnal boundary layer, this traps the chemical species into a smaller

volume thus increasing the concentrations of the chemical species.

- This vertical mixing scheme was implemented into the boxmodel using the same approach of Lourens (2012).
- The mixing ratios of O3, CO and CH4 in the free troposphere were respectively set to
 50 ppbv, 116 ppbv and 1.8 ppmv. These condions were taken from the MATCH-MPIC
 chemical weather forecast model on the 27th March (the start date of the simulations). The
 model results (http://cwf.iass-potsdam.de/) at the 700 hPa height were chosen and the
 daily average was used as input into the boxmodel.

• Tagged free troposphere species were also included in the boxmodel to determine effect of free troposphere species on surface ozone levels.
